A study on optimization of *Penicillium chrysogenum* culture media in Solid state Fermentation process for Pectinase enzyme production

Diptendu Sarkar

Assistant Professor, Department of Life Science, Biotechnology Division, Garden City College, 16th Km, Old Madras Rd, Bangaluru-49, (Karnataka) – India

Abstract

The present research finding has shown that optimization of *Penicillium chrysogenum* culture media in solid state fermentation process for pectinase enzyme production. Four moulds isolated from garden soil samples of Andhrahalli area, Bangalore, Karnataka, India and were screened for pectinolytic enzyme production when grown on pectin containing (YPSS) solid media. *Penicillium chrysogenum* was selected based on clearance zones and pectinase enzyme production was carried out in submerged fermentation. Enzyme production by *Penicillium chrysogenum* was higher at pH 6.0 and a temperature of 30°C using sucrose and ammonium sulphate as carbon source and nitrogen source, respectively. The maximal activity of *P. chrysogenum* pectinase was at 60°C, pH 5.0 and was thermostable up to 70°C. Manganese sulphate had greatest effect on pectinase enzyme activity.

Key-Words: Penicillium chrysogenum, submerged fermentation, Pectinase.

Introduction

The utilization of microbial enzymes has found broad technological application in different industrial processes. Among the various enzymes commercialized many are products of fermentation of filamentous fungi (Piccoli-valle *et al.*, 2001). The genus Penicillium is world wide known for production of secondary metabolites and extracellular enzymes of commercial value, including pectinases.

Pectinase are now an integral part of juice and textile industries (Kashyap et al., 2001) such as maceration of tea leaves (Angayarkanni et al., 2002); processing of cotton fabric (Solbak et al., 2005) as well as in various biotechnological applications (Alkorta et al., 1998, Jacob & Prema, 2006). The filamentous fungi are most often used in the commercial production of pectinases. Microbial production of pectinases has been extensively studied (Kashyap et al., 2001, Torres et al., 2006); actinomycetes (Bruhlmann et al., 1994); Aspergillus flavus (Mellon & Cotty, 2004); Aspergillus sp. (Angayarkanni et al., 2002); Penicilluim italicum (Alana et al., 1990); Penicillium viridicatum RFC3 (Silva et al., 2002); Penicillium roqueforti (Pericin et al., 2007); Penicillium expansum (Cardoso et al., 2007) and Pectolytic moulds (Fawole & Odunfa, 1992).

*Corresponding Author Email: diptendu81@gmail.com ; New enzymes for use in commercial applications with desirable biochemical and physico-chemical characteristics and a low cost production have been the focus of much research (Silva et al., 2002; Malvessi & Silveira, 2004; Phutela et al., 2005). Enzyme breakdown of the biomolecules depends up on the type of enzyme, application, temperature, incubation time, agitation, concentration, pH and use of different enzyme preparations (Dominguez et al., 1994; Chadha et al., 2003). In this context, the objective of the present study was to produce pectinolytic enzymes by a newly isolated strain of Penicillium chrysogenum by submerged fermentation and process evaluation.

Material and Methods

Isolation of fungal species

The 5g of soil sample was collected from Acharya Bangalore B-School girl's hostel garden. A quantity of 1.0 mg of soil from each of the collected samples was dissolved in 9.0 ml of sterile distilled water and serial dilution was plated on MRBA plate with antibiotics to restrict bacterial growth and incubated at 37°c. After the growth of each colony, on the basis of its morphological characteristics was picked up and further purified by repeated streaking on YPSS (Yeast soluble starch agar) agar media. Each fungal culture was then stored in refrigerator for further experiment (Alana *et al.*, 1990: Alkorta *et al.*, 1990).

Screening of soil isolates for pectinolytic activity

A total of 4 isolates from soil were assayed for polygalacturonase (PG) activity using pectincontaining agar medium. Culture plates with pectincontaining agarose were inoculated with each isolate and incubated for 3-5 days at 27°C. After incubation, plates were stained with aqueous 0.05% ruthenium red solution for 30 min and rinsed with distilled water. Culture expressing pectinase activity exhibited a clear zone around the margines of the colony. Macroscopic study a final extension was done by studying growth rate, colour, texture and topography of colony using two standard media namely PDA and Czapek Dox. Microscopic study of Penicillium species was done by preparing slide mount with lacto phenol cotton blue stain and observed under light microscope (Alana et al., 1990: Alkorta et al., 1990).

Enzyme production by submerged fermentation

The fungal culture was used to produce pectinase enzyme using liquid medium (g/L) containing citrus pectin – 10g/L; (NH₄)₂SO₄ -1.4g/L; K₂HPO₄ - 6g/L; MgSO₄.7H₂O – 0.1g/L; pH - 6. Fermentation was carried out in 500mL conical flask containing 250mL of growth medium with 10% inoculum and incubated at 30°C under shaking conditions (175 rpm) for 4 days. The biomass was separated by centrifugation at 10,000 *g for 15min at 4°C. The supernatant was used to evaluate the pectinase enzyme activity.

Culture conditions

The culture conditions [pH between 6 to 8, temperature from 30°C to 50°C, different carbon sources like dextrose, mannitol, sucrose and starch and nitrogen sources like ammonium sulphate, ammonium nitrate, ammonium chloride & peptone] on selected pectinase enzyme production was studied.

Pectinase enzyme assay

The polygalacturonase activity was determined by measuring the amount of reducing substances liberated from citrus pectin. The reaction mixture consisted of substrate buffer (0.125 g citrus pectin dissolved in 25 mL of 0.2 M sodium citrate buffer, pH 6.5) and enzyme solution (0.5 mL). This mixture was incubated at 37°C for 30 min., heated in a oiling water bath for 5 min and the reaction was stopped by using 3 mL of DNS reagent. The absorbance was read at 570 nm. One unit of enzyme activity (U) was defined as 1 μ mol of galacturonic acid released per min (Silva *et al.*, 2002).

Protein content

Protein content was determined by the method of Lowry *et al.*, (1951), using Bovine Serum Albumin (BSA) as standard.

Results and Discussion Screening of isolates

Four fungal species isolated from garden soil sample and morphological characteristics were examined. Fungal isolates were further screened by yeast soluble starch agar (YPSS) plate method and the zone of clearance was calculated. *Penicillium chrysogenum* culture had a zone of clearance above 3cm. On the basis of screening method, the isolate *Penicillium chrysogenum* found to be a potential source of pectinolytic enzyme. This culture was used for optimization of pectinase production using shake flask submerged fermentation process.

Fig. 2: *Penicillium chrysogenum* showing *chrysogenum* zone of clearance maximum Optimization of culture conditions

The temperature and pH of the cultivation medium are important factors in the pectinase production, which may influence the sort and content of those enzymes produced by filamentous fungus. The strong effect of pH on the production of endo pectinase was clearly observed in flask cultures, where pH value 6-8, and temperature 30°C-50°C were tested for crude enzyme production (Fig 3,4,5) . The maximum pectinase activity was found with an initial pH of 6 at temperature 30°C, activity reaching 0.696 µg/ml/min

on fifth day of incubation. When the temperature was maintained at 40°C and 50°C with pH 6, the enzyme activity was found to be 0.516 µg/ml/min and 0.468 µg/ml/min respectively on fifth day of incubation. By keeping the pH constant at pH 7, the enzyme activity was measured as 0.576 µg/ml/min at 30°C, 0.504 at 40°C and 0.396 µg/ml/min at 50°C whereas by keeping pH 8 as constant, it was seen that the enzyme activity was found to be 0.612 µg/ml/min at 30°C, 0.444 µg/ml/min at 40°C and 0.336 µg/ml/min at 50°C. So optimum pH for enzyme production was found to be 6 and optimum temperature was found to be 30°C. Either increase or decrease beyond the optimum value show decline in enzyme production. However, the mechanism by which the pH and temperature both acts on the same time for the production of pectic enzyme is not clearly known. Piccolo-valle et al., (2001) observed that a high pectinase and pectin esterase activity was showed by *P.griseoroseum* in more acid pH of 4.5 and 5 and of Pectin Lyase, pH was closed to the neutral 5-7. P.viridicatum showed maximum production of polygalacturonase and Pectin Lyase at pH 4.5 and 5 respectively (Silva et al., 2002). The temperature optima of 30°C, was obtained from a purified culture fluid of *P.frequentans* by Chellegatti (2002). This can give the support to our obtained result.From the observation it was clear that 30°C was the optimum for the growth of micro organisms, temperature variation was done in different pH and it was seen that pH 6 was optimum (Fig 3,4,5).

Fig. 3: Enzyme Activity measured at different temperatures keeping pH 6

Fig. 5: Enzyme Activity measured at different temperatures keeping pH 8

Supplementation of different carbohydrate sources (dextrose, mannitol, sucrose and starch) to the production medium increase the pectinolytic activity of P.chrysogenum (Fig 6.7). When pH 6 and temperature 30°C (both optimum for production) were maintained constant in production medium, the different carbohydrate sources showed different effect on pectinase production respectively. In presence of sucrose the crude production was maximum (13.7 µg/ml) and enzyme activity was found 0.876 µg/ml/min. In case of dextrose, mannitol and starch, the production was found 10.2µg/ml, 9.7µg/ml and 5.8µg/ml respectively and enzyme activity was found 0.732µg/ml/min, 0.636µg/ml/min and 0.516µg/ml/min respectively. So from our data it can be concluded that the pectinase production rate was highly repressed in

Fig. 6: Graph to show the enzyme activity with different carbohydrates

Of the different nitrogenous sources (ammonium sulphate, ammonium nitrate, ammonium chloride and peptone) used, peptone has enhanced the production of *P.chrysogenum* pectinase when medium optimum pH and temperature were 6 and 30°C respectively (Fig 8,9). Phutela *et al.*, (2005) reported that peptone followed by ammonium sulphate stimulated pectinase production more, as in their absence fungus displayed a slight proteolytic activity and did not produce extracellular pectinases.

Fig. 9: Graph showing Protein concentration with different nitrogen sources

Different metals (zinc sulphate, magnesium sulphate, manganese sulphate and ferrous sulphate) influenced on enzyme activity was also studied (Fig 10). Optimal activity was observed at 1mg/ml of manganese sulphate (0.888μ g/mL/min) and least activity was found in presence of 1mg/ml of zinc sulphate (0.348μ g/mL/min). It may be suggested that the active sight of pectinase was influenced by magnesium sulphate to catalyse the hydrolytic reactions and negative cooperativity was shown by zinc sulphate (Hla *et al.*, 2005).

Fig. 10: Enzyme activity after addition of various metals

The pectinase activity of *P.chrysogenum* was found to be highest at pH 6.0 using phosphate buffer. Marcia et al.,(1999) studied the stability of pectinase against different pH. Their result indicated that the enzyme was stable in a pH 6-8 and showed highest activity at pH 5.0. Martin et al., (2002) reported that pectinase from Penicillium sp. was stable at pH range of 3-8 and maintained 70% of initial activity at 70°C. In this study, pectinase produced by P.chrysogenum was stable in neutral pH (6-8) and was stable in temperature 60°C. Different metals (zinc sulphate, magnesium sulphate, manganese sulphate and ferrous sulphate) influenced on enzyme activity was also studied. Optimal activity was observed at 1mg/ml of manganese sulphate (0.888µg/mL/min) and least activity was found in presence of 1mg/ml of zinc sulphate (0.348µg/mL/min). It may be suggested that the active sight of pectinase was influenced by magnesium sulphate to catalyse the hydrolytic reactions and negative cooperativity was shown by zinc sulphate (Hla et al., 2005).

Conclusion

Pectinase enzyme was isolated from the native strain, *P. chrysogenum* that can be used for various industrial applications including extraction and clarification of fruit juices, processing of cotton fabric in textile industries, bleaching of paper, removal of pectic waste waters and maceration of tea leaves.
