Abstract
Coka Dam Papara is big water body rich in flora and Fauna also used for fish culture under the control of Department of Fishries Govt. of M.P. Composite fish cultures were conducted in Coka Dam Papara Satna in 2.3 hectare water area. *Amblypharyngodon mola* (Ham.) *Puntius chola* (Ham.) *Cirrhinus mrigala* (Ham.) and *Labeo calbasu* (Ham.) were cultured under experimental and control Coka Dam in the pH of water of the experimental area was within 5.5-8.5 the limestone containing 55-66% Cao and dolomite containing 30-32% Cao at were used for raising the water pH level. Application of dolomite helps to increase the water retention capacity of the Coka Dam. Niger was observed higher in experimental Coka Dam than the control one.

Key-Words: Coka Dam, Fish, Growth, Production, Satna

Introduction
The fresh water bodies are spread over diverse Geo climatic regions. They are exposed to various climatic conditions and received drainage from different of catchments areas. The hydrogen-ion concentration (pH) of natural waters is an important environmental factor for the growth of fishes. Increases in the concentration of $H^+$ ions results lower pH value and low $H^+$ ions concentration brings about higher pH value. The pH of water is the logarithm of the reciprocal of hydrogen ion concentration. The objective of this study was to find out the effects of pH of water on the production of fish in composite fish culture. Demand of fishes is increasing day by day. Production of fish depends on the application of required amount of organic and inorganic fertilizer which are helpful to increase the natural fish food. Optimin level of water quality such as dissolved oxygen, alkalinity, hardness and pH are also the prerequisite for fish production. Among which pH of water has an important role for enhancement of fish yield. Lime fertilizers such as lime stone containing 55-66% Cao, dolomite lime stone containing 42-55% Cao, and dolomite containing 30-32% Cao are generally used for raising the water pH level to required doses. Natural water of Satna district in Madhya Pradesh is mostly acidic, having pH ranging from 4.0 to 5.5.

To find out the effects of pH on fish growth and production the fresh water Coka Dam were selected for composite fish culture of four species. Expected yield was observed for grass carp *Cirrhinus Mrigala* and *Labeo calbasu* in the Coka Dam. The growth rate and production of Indian major carps, *Amblypharyngodon mola* (Ham.), *Puntius chola* (Ham.), *Cirrhinus mrigala* and *Labeo calbasu* (Ham.) per unit area were evaluated. The various works have been made as per method suggested by Dutt, et al (2001), and George (1969).

Geography of Coka Dam
Coka Dam is situated in municipal area of Satna town, located on south west part of Madhya Pradesh. It is an important district of Ex- Vindhya Madhya Pradesh State and part of Baghelkhand rele of Second century A.D. Satna district is a pilgrim and an industrial place, area rich in Limestone, Bauxite, White clay, Geru, Ramraj and Flagstones. It is also famous for its religious places of Chitrakoot. The district Satna is the central part of Vindhya region which is surrounded by the boundaries of Rewa and Satna on the North, Bilaspur district on the South and Jabalpur on the West side.
Material and Methods

Fish sampling were collected from the Coka dam district Satna in three distinct season viz. summer monsoon and winter. Summer extends from March to June. Water samples were collected at 1st of each month for all five sites. The of water samples directly measured by digital pH meter. Collected fish during sampling were preserved in 10% formalin and were identified with the help of as per eminent workers (APHA, 1995; Mishra, 1968).

Results and Discussion

The fish production of fresh water was selected at Coka Dam Dist. Satna Madhya Pradesh having 2.3 hectare water area of composite fish culture. One of which was used as experimental Coka Dam and the other as control Coka Dam, Dolomite 5470 kg./ha containing 30-32% CaO and limestone 2500 kg./ha containing 55-56% CaO were applied to the experimental Coka Dam. pH of water was maintained within 5.5-8.5. The pH of water of control Coka Dam was maintained within 3.5-5.5. Dolomite has played an important role to minimize the water seepage. It has been recorded that the pH of water of Coka Dam varies during March to June. It is established that water having pH ranges between 5.5-8.0 have been most suitable for inland Coka Dam fish culture and pH value more than 8.5 was found to be unsuitable as CO₂ in not available. Mortality of fishes occurs at about pH. In Acid waters lose their appetite, growth capacity and tolerance to toxic substances. Toxic effects of H₂S₂ copper and other heavy metals to fish increase by lowering the pH of water. Indian major carps prefer to feed the aquatic organisms as their food. In control Coka Dam low yield of the Indians major carps maybe due to 10 pH of water than the experimental one. The acid in water may indirectly harmful effect on aquatic organisms which was used as natural food by fishes. On the contrary the yield of grass carp and silver carp were almost same in both experimental areas there form low pH of water may not have low productive effects on the growth and production of these two exotic carps. The similar observations have been made by Bhatt (1968), Singh (2007), Welch, (1948), Das (1957), David (1963), Dattamunshi & Shrivastava (1988), Faiace (1978), and Fulton (1904).

Acknowledgement

We are thankful to my praiseworthy Principal Dr. Y.P. Singh and Dr. A.K. Tiwari Prof. Zoology for suggestions extends help and permission wherever desire. Thanks are also due to Ichthyologist of Zoology Department by which the work come into this shape.
